What is claimed is:

1. Apparatus for mounting an electronic component to a wall of a structure such as a home or an office, comprising:

a support plate, the support plate including a grid of holes therein, the grid being formed to have a pair of columns of the holes, the columns being spaced apart by a selected distance and the holes in each of the columns being spaced apart by a predetermined interval;

means for mounting the support plate to the wall, the support plate being formed such that the grid is spaced apart from the wall;

a module formed generally as a plate such that an electronic component may be mounted thereto, the module including:

a pair of hooks extending from a first edge thereof, the hooks being spaced apart by the column spacing such that the hooks may be arranged to extend through first and second holes in the grid;

a locking pin extending from the module such that the locking pin extends into a corresponding third hole in the grid to restrain the module against movement parallel to the support plate; and

the module further including a passage that is aligned with a fourth hole in the grid when the hooks and locking pin are in their respective holes; and

a locking pin configured for insertion into the passage and through the fourth hole in the grid, the locking pin being arranged to restrain the module against movement away from the support plate.

2. The apparatus of claim 1 further comprising:

a second pair of columns of holes formed in the support plate, the second pair of columns being substantially identical to the first pair of columns and arranged to be parallel thereto; and

a pair of flanges extending from opposite sides of the support plate, the flanges being configured to receive fasteners for mounting the support plate to a pair of wall studs.
